HMM POS Tagging

- Modelo probabilístico sequencial
- Computa a probabilidade para possíveis sequências de rótulos
- Escolhe a melhor sequência

Hidden Markov Model

- Rótulos estão escondidos (hidden)
- Observa palavras
- Inferir rótulos (ex. POS) da sequência de palavras
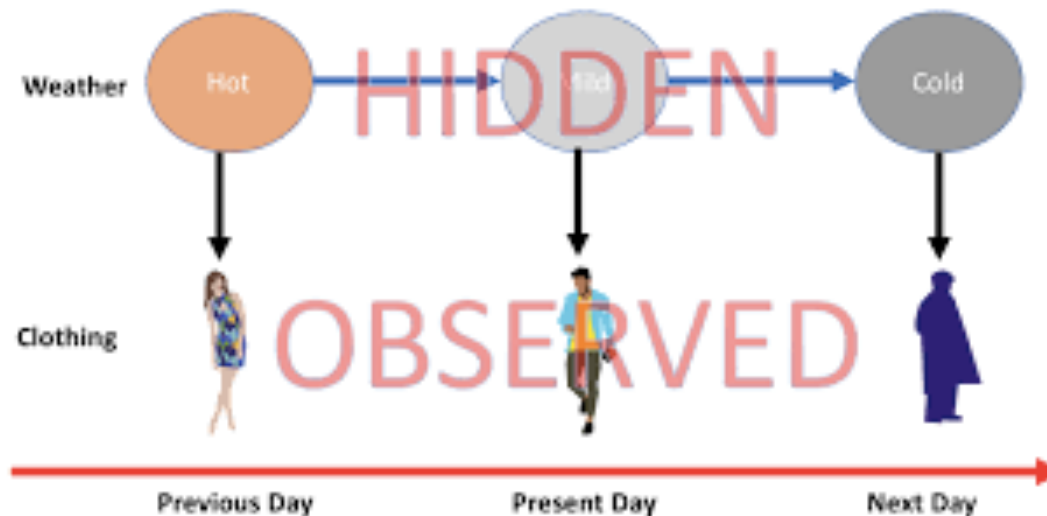

Markov Chain

- Probabilidade do próximo rótulo só depende do anterior

$$P(q_i = a | q_1 ... q_{i-1}) = P(q_i = a | q_{i-1})$$
Hidden Markov Model: Componentes

$Q = q_1 q_2 \ldots q_N$ — a set of N **states**

$A = a_{11} \ldots a_{ij} \ldots a_{NN}$ — a **transition probability matrix** A, each a_{ij} representing the probability of moving from state i to state j, s.t. $\sum_{j=1}^{N} a_{ij} = 1 \quad \forall i$

$O = o_1 o_2 \ldots o_T$ — a sequence of T **observations**, each one drawn from a vocabulary $V = v_1, v_2, \ldots, v_V$

$B = b_i(o_t)$ — a sequence of **observation likelihoods**, also called **emission probabilities**, each expressing the probability of an observation o_t being generated from a state q_i

$\pi = \pi_1, \pi_2, \ldots, \pi_N$ — an **initial probability distribution** over states. π_i is the probability that the Markov chain will start in state i. Some states j may have $\pi_j = 0$, meaning that they cannot be initial states. Also, $\sum_{i=1}^{n} \pi_i = 1$

Markov Assumption: $P(q_i | q_1, \ldots, q_{i-1}) = P(q_i | q_{i-1})$

Output Independence: $P(o_i | q_1, \ldots q_i, \ldots, q_T, o_1, \ldots, o_i, \ldots, o_T) = P(o_i | q_i)$

HMM Tagger

Citing high fuel prices, [ORG United Airlines] said [TIME Friday] it has increased fares by [MONEY $6] per round trip on flights to some cities also served by lower-cost carriers. [ORG American Airlines], a unit of [ORG AMR Corp.], immediately matched the move, spokesman [PER Tim Wagner] said. [ORG United], a unit of [ORG UAL Corp.], said the increase took effect [TIME Thursday] and applies to most routes where it competes against discount carriers, such as [LOC Chicago] to [LOC Dallas] and [LOC Denver] to [LOC San Francisco].
